(Received 31 July 2009; published 17 February 2010)

We consider a particular type of parametrically driven discrete Klein-Gordon system describing microdevices and nanodevices, with integrated electrical and mechanical functionality. Using a multiscale expansion method we reduce the system to a discrete nonlinear Schrödinger equation. Analytical and numerical calculations are performed to determine the existence and stability of fundamental bright and dark discrete solitons admitted by the Klein-Gordon system through the discrete Schrödinger equation. We show that a parametric driving can not only destabilize onsite bright solitons, but also stabilize intersite bright discrete solitons and onsite and intersite dark solitons. Most importantly, we show that there is a range of values of the driving coefficient for which dark solitons are stable, for any value of the coupling constant, i.e., oscillatory instabilities are totally suppressed. Stability windows of all the fundamental solitons are presented and approximations to the onset of instability are derived using perturbation theory, with accompanying numerical results. Numerical integrations of the Klein-Gordon equation are performed, confirming the relevance of our analysis.

I. INTRODUCTION

Current advances in the fabrication and control of electromechanical systems on microscale and nanoscale bring many technological promises [1]. These include efficient and highly sensitive sensors to detect stresses, vibrations, and forces at the atomic level; to detect chemical signals; and to perform signal processing [2]. As a particular example, a nanoelectromechanical system (NEMS) can detect the mass of a single atom due to its own very small mass [3,4].

On a fundamental level, NEMS with high frequency will allow research on quantum-mechanical effects. This is because NEMS, as a miniaturization of microelectromechanical systems (MEMS), can contain a macroscopic number of atoms, yet still require quantum mechanics for their proper description. Thus, NEMS can be considered as a natural playground for a study of mechanical systems at the quantum limit and quantum-to-classical transitions (see, e.g., Ref. [5] and references therein).

Typically, nanoelectromechanical devices comprise an electronic device coupled to an extremely high-frequency nanoresonator. A large number of arrays of MEMS and NEMS resonators have recently been fabricated experimentally (see, e.g., Ref. [6]). One direction of research in the study of such arrays has focused on intrinsic localized modes (ILMs) or discrete breathers. ILMs can be present due to parametric instabilities in an array of oscillators [7]. ILMs in driven arrays of MEMS have been observed experimentally [8–10].

Motivated by a recent experiment of Buks and Roukes [6] that succeeded in fabricating and exciting an array of MEMS and measuring oscillations of the resonators, here we consider the equation [11]

\[ \psi_n = D \Delta_2 \psi_n - \left[ 1 - H \cos(2\alpha_0 t) \right] \psi_n + \varphi_n^3, \] (1)

which governs the oscillation amplitude of such an array. Equation (1) is a simplified model of that discussed in Ref. [12], subject to an assumption that the piezoelectric parametric drive is applied directly to each oscillator [13]. The variable \( \varphi_n \) represents the oscillation amplitude of the \( n \)th oscillator from its equilibrium position, \( D \) is a dc electrostatic nearest-neighbor coupling term, \( H \) is a small ac component with frequency \( 2\alpha_0 \) responsible for the parametric driving, \( \Delta_2 \psi_n = \psi_{n+1} - 2\psi_n + \psi_{n-1} \) is the discrete Laplacian, the overdot denotes the derivative with respect to \( t \), and the “plus” and “minus” signs of the cubic term correspond to “softening” and “stiffening” nonlinearities, respectively. Here, we assume ideal oscillators, so there is no damping present. The creation, stability, and interactions of ILMs in Eq. (1) with low damping and in the strong-coupling limit have been investigated in Ref. [11]. Here, we extend that study to the case of small coupling parameter \( D \).

In performing our analysis of the governing Eq. (1), we introduce a small parameter \( \epsilon \ll 1 \) and assume that the following scalings hold:

\[ D = \epsilon^3 3C, \quad H = \pm \epsilon^2 3\gamma, \quad \alpha_0 = 1 \pm \epsilon^2 3\Lambda/2. \]

We then expand each \( \varphi_n \) in powers of \( \epsilon \), with the leading-order term being of the form

\[ \varphi_n \sim \epsilon [ \psi_n(T_2,T_3,...)e^{-iT_0} + \bar{\psi}_n(T_2,T_3,...)e^{iT_0}]. \] (2)

where \( T_2 = \epsilon^2 t \). Then the terms at \( O(\epsilon^4 e^{-iT_0}) \) in Eq. (1) yield the following equation for \( \psi_n \) (see Refs. [14,15] for a related reduction method):

\[ -2i \psi_n = 3C \Delta_2 \psi_n + 3 \bar{\gamma} \psi_n e^{\pm i3\Lambda T_2} \pm 3 |\psi_n|^2 \psi_n, \] (3)

where the overdot now denotes the derivative with respect to \( T_2 \). Correction terms in Eq. (2) are \( O(\epsilon^6 e^{\pm i(k+1)T_0}) \) and \( e^{\pm i(k-1)T_0} \), with \( k \in \mathbb{Z}^+ \). A justification of this rotating-wave-type approximation can be obtained in, e.g., Ref. [16].

*On leave from Department of Mathematics, Faculty of Mathematics and Natural Sciences, Andalas University, Limau Manis, Padang 25163, Indonesia.
Writing \( \psi_n(T_2) = \phi_n(T_2)e^{\pm i\delta T_2} \), we find that Eq. (3) becomes
\[
-\frac{2}{\delta}i\phi_n = C\Delta_2\phi_n + \Lambda\phi_n + \gamma\phi_n \pm |\phi_n|^2\phi_n.
\]
(4)

Then, taking \( T_2 = \frac{2}{\delta}t \), we find that the equation above becomes the parametrically driven discrete nonlinear Schrödinger (DNLS) equation
\[
i\dot{\phi}_n = -C\Delta_2\phi_n + \Lambda\phi_n + \gamma\phi_n \pm |\phi_n|^2\phi_n.
\]
(5)

Here, the overdot denotes the derivative with respect to \( \dot{t} \).

The present paper is organized as follows. In Sec. II we present the existence and stability analysis of onsite and intersite bright solitons. Analysis of dark solitons is presented in Sec. III. Confirmation of this analysis, through numerical simulations of the Klein-Gordon system (1), is given in Sec. IV. Finally, we give conclusions in Sec. V.

II. BRIGHT SOLITONS IN THE FOCUSING DNLS

In this section we first consider the existence and stability of bright solitons in the focusing DNLS equation. For a static solution of Eq. (5) of the form \( \phi_n = u_n \), where \( u_n \) is real valued and time independent, it follows that
\[
- C\Delta_2 u_n - u_n^3 + \Lambda u_n + \gamma u_n = 0.
\]
(6)

Once such discrete solitary-wave solutions of Eq. (5) have been found, their linear stability is determined by solving a corresponding eigenvalue problem. To do so, we introduce the linearization ansatz
\[
\phi_n = u_n + \delta \tilde{\epsilon}_n,
\]
where \( \delta \ll 1 \), and substitute this into Eq. (5) to yield the following linearized equation at \( O(\delta) \):
\[
i\dot{\epsilon}_n = -C\Delta_2 \epsilon_n - 2|u_n|^2 \epsilon_n - u_n^2 \bar{\epsilon}_n + \Lambda \epsilon_n + \gamma \bar{\epsilon}_n.
\]
(7)

Writing \( \epsilon_n(t) = \eta_n + i \tilde{\epsilon}_n \), we then obtain from Eq. (7) the eigenvalue problem
\[
\begin{bmatrix}
\eta_n \\
\tilde{\epsilon}_n
\end{bmatrix}
= \mathcal{H}
\begin{bmatrix}
\eta_n \\
\tilde{\epsilon}_n
\end{bmatrix},
\]
(8)

where
\[
\mathcal{H} = \begin{pmatrix}
0 & \mathcal{L}_+(C) \\
-\mathcal{L}_-(C) & 0
\end{pmatrix},
\]

and the operators \( \mathcal{L}_+(C) \) and \( \mathcal{L}_-(C) \) are defined by
\[
\mathcal{L}_+(C) = -C\Delta_2 - (3u_n^2 - \Lambda - \gamma),
\]
\[
\mathcal{L}_-(C) = -C\Delta_2 - (u_n^2 - \Lambda + \gamma).
\]

The stability of the solution \( u_n \) is then determined by the eigenvalues of Eq. (8). If we denote these eigenvalues by \( \omega \), then the solution \( u_n \) is stable only when \( \text{Im}(\omega) = 0 \) for all eigenvalues \( \omega \).

We note that, because Eq. (8) is linear, we may eliminate one of the eigenvectors, for instance \( \eta_n \), to obtain an alternative expression of the eigenvalue problem in the form
\[
\mathcal{L}_+(C)\mathcal{L}_-(C)\eta_n = \omega^2 \eta_n = \Omega \eta_n.
\]
(9)

In view of the relation \( \Omega = \omega^2 \), it follows that a soliton is unstable if it has an eigenvalue with either \( \Omega < 0 \) or \( \text{Im}(\Omega) \neq 0 \).

A. Analytical calculations

Analytical calculations of the existence and stability of discrete solitons can be carried out for small coupling con-
In studying the stability problem, it is natural to also expand one of the three values given by
\[ \text{resulting in the eigenvalue } \eta_n, \]
in the values and the continuous spectrum of a stable onsite bright soliton with either \( \Omega < 0 \) or \( \text{Im}(\Omega) \neq 0 \).

Solutions of Eq. (6) for small \( C \) can then be calculated analytically by writing
\[ u_n = u_n^{(0)} + C u_n^{(1)} + C^2 u_n^{(2)} + \cdots . \]
In studying the stability problem, it is natural to also expand the eigenvector \( \eta_n \) and the eigenvalue \( \Omega \) in powers of \( C \), as
\[ \eta_n = \eta_n^{(0)} + C \eta_n^{(1)} + \mathcal{O}(C^2), \quad \Omega = \Omega^{(0)} + C \Omega^{(1)} + \mathcal{O}(C^2). \]
Upon substituting this expansion into Eq. (9) and identifying coefficients of successive powers of the small parameter \( C \), we obtain from the equations at \( \mathcal{O}(1) \) and \( \mathcal{O}(C) \) the results
\[ [\mathcal{L}_s(0)\mathcal{L}_c(0) - \Omega^{(0)}] \eta_n^{(0)} = 0, \]
where\[ f_n = (\Delta_2 + 2 u_n^{(0)} u_n^{(1)}) \mathcal{L}_c(0) + \mathcal{L}_s(0)(\Delta_2 + 6 u_n^{(0)} u_n^{(1)}) + \Omega^{(1)}. \]
In the uncoupled limit, \( C=0 \), the eigenvalue problem is thus simplified to
\[ \Omega^{(0)} = \mathcal{L}_s(0)\mathcal{L}_c(0), \]
from which we conclude that there are two possible eigenvalues, given by

![FIG. 1. (Color online) A sketch of the dynamics of the eigenvalues and the continuous spectrum of a stable onsite bright soliton in the (Re(\Omega), Im(\Omega)) plane. The arrows indicate the direction of movement as the coupling constant \( C \) increases. Note that a soliton is unstable if there is some \( \Omega \) with either \( \Omega < 0 \) or \( \text{Im}(\Omega) \neq 0 \).](image1)

![FIG. 2. (Color online) As Fig. 1, but for a stable intersite bright soliton.](image2)

![FIG. 3. (Color online) The (in)stability region of onsite bright solitons in (\( C, \gamma \)) space. For each value of \( C \) and \( \gamma \), the corresponding color indicates the maximum value of \( \text{Im}(\omega) \) (over all eigenvalues \( \omega \)) for the steady-state solution at that point. Stability is therefore indicated by the region in which \( \text{Im}(\omega)=0 \), namely, the dark region. White dashed and dashed-dotted lines give the analytical approximations (20) and (21), respectively.](image3)

\[ [\mathcal{L}_s(0)\mathcal{L}_c(0) - \Omega^{(0)}] \eta_n^{(1)} = f_n \eta_n^{(0)}, \]

where
\[ f_n = (\Delta_2 + 2 u_n^{(0)} u_n^{(1)}) \mathcal{L}_c(0) + \mathcal{L}_s(0)(\Delta_2 + 6 u_n^{(0)} u_n^{(1)}) + \Omega^{(1)}. \]

![FIG. 4. Comparison between the critical eigenvalues of intersite bright solitons obtained numerically (solid lines) and their analytical approximation (dashed lines). The upper and lower curves correspond, respectively, to \( \gamma=0.5 \) and 0.1, approximated by Eq. (24), whereas the middle one corresponds to \( \gamma=0.18 \), approximated by Eq. (25).](image4)
which correspond, respectively, to the solutions $u_n^{(0)}=0$ (for all $n$) and $u_n^{(0)}=\pm \sqrt{\Lambda + \gamma}$ (for all $n$).

We begin by considering bright soliton solutions, for which $u_n\to 0$ as $n\to \pm \infty$. This then implies that (for $C=0$) the eigenvalue $\Omega_n^{(0)}$ has infinite multiplicity; it generates a corresponding continuous spectrum (phonon band) for finite positive $C$. To investigate the significance of this continuous spectrum, we introduce a plane-wave expansion

$$\eta_n = a e^{i\kappa n} + b e^{-i\kappa n},$$

from which one obtains the dispersion relation

$$\Omega = [2C(\cos \kappa - 1) - \Lambda]^2 - \gamma^2. \quad (15)$$

This in turn shows that the continuous band lies between

$$\Omega_L = \Lambda^2 - \gamma^2, \quad \text{when} \quad \kappa = 0, \quad (16)$$

FIG. 5. The structure of the eigenvalues of intersite bright solitons in the complex plane for three values of $\gamma$, as indicated in the caption of each plot. Left and right panels depict the eigenvalues of stable and unstable solitons, respectively.

\[ \Omega^3 = \Lambda^2 - \gamma^2 + 8C(\Lambda + 2C), \quad \text{when } \kappa = \pi. \quad (17) \]

From the continuous spectrum analysis above, it can be concluded that an instability can only be caused by the dynamics of the discrete spectrum.

1. Onsite bright solitons

The existence and stability of a single excited state, i.e., an onsite bright soliton, in the presence of parametric driving have been considered in Ref. [26]. For small \( C \), the soliton is given by

\[ u_n = \begin{cases} \sqrt{\Lambda + \gamma + C/\Lambda + \gamma + O(C^2)}, & n = 0 \\ C/\Lambda + \gamma + O(C^2), & n = -1,1 \\ O(C^2), & \text{otherwise}, \end{cases} \quad (18) \]

and its eigenvalue is given by

\[ \Omega_E = 4(\Lambda + \gamma)\gamma + 8\gamma C + O(C^2). \quad (19) \]

It was shown in Ref. [26] that configuration (18), which is known to be stable for any value of \( C \) when \( \gamma = 0 \), can be destabilized by parametric driving. Furthermore, it was shown that there are two mechanisms of destabilization, as sketched in Fig. 1. The two instability scenarios are determined by the relative positions of \( \Omega_E^{(0)} \) and \( \Omega_C^{(0)} \), as we now summarize. First, we note that there is a threshold value, \( \gamma_{th} = \Lambda/5 \), at which the two leading-order eigenvalues coincide, so that \( \Omega_E^{(0)} = \Omega_C^{(0)} \). For \( \gamma > \gamma_{th} \), upon increasing \( C \) from \( C = 0 \), the instability is caused by the collision of \( \Omega_E \) with \( \Omega_U \); taking \( \Omega_E = \Omega_U \) then yields the corresponding approximate critical value

\[ \gamma_{cr,1} = -\frac{2}{3} \Lambda - \frac{4}{15} C + \frac{1}{15} \sqrt{9\Lambda^2 + 56CA + 96C^2}. \quad (20) \]

For \( \gamma < \gamma_{th} \), by contrast, the instability is caused by the collision of \( \Omega_E \) with an eigenvalue bifurcating from \( \Omega_L \). In this case, the critical value of \( \gamma \) can be approximated by taking \( \Omega_E = \Omega_L \), giving

\[ \gamma_{cr,2} = -\frac{2}{5} \Lambda - \frac{4}{15} C + \frac{1}{15} \sqrt{9\Lambda^2 + 16C(\Lambda + C)}. \quad (21) \]

Together, \( \gamma_{cr,1} \) and \( \gamma_{cr,2} \) give approximate boundaries of the instability region in the \((C, \gamma)\) plane.

FIG. 6. (Color online) As Fig. 3, but for intersite bright solitons. Our analytical approximations, given by Eqs. (25)–(27), are shown as white dashed-dotted, dotted, and dashed lines, respectively.

\[ \gamma < 0.5\Lambda \]

\[ \Omega^3 = \Omega_L \Omega_U \Omega_E \]

\[ \gamma > 0.5\Lambda \]

\[ \Omega^3 = \Omega_U \Omega_L \Omega_E \]

FIG. 7. (Color online) As Fig. 1, but for a stable onsite dark soliton.
The solvability condition. The Fredholm alternative requires that the double eigenvalue splits into two distinct eigenvalues, which are given as functions of $C$ by

$$\Omega_1 = 4(\Lambda + \gamma)\gamma + 4\gamma C + O(C^2),$$

$$\Omega_2 = 4(\Lambda + \gamma)\gamma - 4(\Lambda + \gamma)C + O(C^2).$$

As is the case for onsite discrete solitons, intersite bright solitons can also become unstable. The mechanism of the instability is again determined by the relative positions of $\Omega_1^{(0)}$ and $\Omega_2^{(0)}$, as sketched in Fig. 2. Performing an analysis corresponding to that in Ref. [26], we find that the two mechanisms of destabilization for an onsite discrete soliton also occur here. The two scenarios have corresponding critical values of $\gamma$, which are given as functions of $C$ by

$$\gamma_{cr,1} = -\frac{2}{5}\Lambda + \frac{2}{5}C + \frac{1}{5}\sqrt{9\Lambda^2 + 52AC + 84C^2},$$

$$\gamma_{cr,2} = -\frac{2}{5}\Lambda - \frac{2}{5}C + \frac{1}{5}\sqrt{9\Lambda^2 + 8AC + 4C^2}.$$

We emphasize, as is apparent from the sketch shown in Fig. 2, that there is another possible mechanism of destabilization for $\gamma < \gamma_{th}$, namely, when $\Omega_2$ becomes negative. The third critical choice of parameter values is then obtained by setting $\Omega_2=0$, i.e.,
FIG. 11. (Color online) The (in)stability region of onsite dark solitons in the two-parameter \((C, \gamma)\) space. The white solid and dashed lines, respectively, give the analytical approximations (43) and (46). White dashed-dotted and dotted lines show Eqs. (42) and (45); note that these curves are indistinguishable in this plot.

\[ \gamma_{cr,3} = C. \]  

Furthermore, by solving \( \gamma_{cr,2} = \gamma_{cr,3} \) we find that \( \gamma = (\sqrt{15} - 2)\Lambda/9 \), which then gives a more specific domain of \( \gamma \)'s for the two possible scenarios of destabilization above.

B. Comparisons with numerical calculations

We have solved the steady-state equation (6) numerically using a Newton-Raphson method and analyzed the stability of the numerical solution by solving the eigenvalue problem (8). In this section, we compare these numerical results with the analytical calculations of the previous section. For the sake of simplicity, we set \( \Lambda = 1 \) in all the illustrative examples.

1. Onsite bright solitons

Comparisons between numerical calculations and analytical approximations for the case of onsite bright solitons have been fully presented and discussed in Ref. [26]. For the sake of completeness, we reproduce the results of Ref. [26] for the (in)stability domain of onsite solitons in the \((C, \gamma)\) plane in Fig. 3. Approximations (20) and (21) are also shown there.

2. Intersite bright solitons

For the stability of intersite bright solitons, we start by examining the validity of our analytical prediction for the eigenvalue associated with the phase mode as given by Eqs. (23) and (24). In Fig. 4, we present a comparison between the analytical approximation and the numerics for some representative values of \( \gamma \) (specifically \( \gamma = 0.1, 0.18, 0.5 \)). This figure reveals the relative accuracy of the small-\( C \) approximations, and we conclude that their range of validity is wider for smaller values of \( \gamma \).

Next we turn to a description of the eigenvalue structure of this intersite configuration for the three values of \( \gamma \) given above; this is shown in Fig. 5, where the left and right panels, respectively, present the structure just before and just after the first collision that results in the mode instability. We now describe results in more detail for the three values of \( \gamma \) in turn.

For \( \gamma = 0.1 \), when \( C = 0 \) the eigenvalues \( \omega \) lie in the gap between the two parts of the continuous spectrum, and the instability is caused by a collision between the critical eigenvalue and its twin at the origin (see the top panels of Fig. 5). For \( \gamma = 0.18 \), the eigenvalues \( \omega \) also lie in the gap between the two parts of the continuous spectrum, but the instability in this case is due to a collision between one of the eigenvalues and the inner edge of the continuous spectrum at \( \omega = \pm \sqrt[3]{\Omega} \) (see the middle panels of Fig. 5). In contrast to the two cases above, for \( \gamma = 0.5 \) the eigenvalues lie beyond the continuous spectrum, and the instability is caused by a collision between the critical eigenvalue and the outer boundary at \( \omega = \pm \sqrt[3]{\Omega} \) (see the bottom panels of Fig. 5). All the numerical results presented here are in accordance with the sketch shown in Fig. 2.

Numerical calculations of the stability of intersite bright solitons, for a relatively large range of \( C \) and \( \gamma \), give us the (in)stability domain of the bright solitons in the two-parameter \((C, \gamma)\) plane, which is presented in Fig. 6. We use colors to represent the maximum of \(|\text{Im}(\omega)|\) as a function of \( C \) and \( \gamma \); thus, solitons are stable in the black region. Our analytical predictions for the occurrence of instability, given by Eqs. (25)–(27), are also shown, respectively, by dashed, dotted, and dashed-dotted lines.

III. DARK SOLITONS IN THE DEFOCUSING DNLS

In this section we consider the existence and stability of onsite and intersite dark solitons for the defocusing DNLS equation. Then a static (real-valued time-independent) solution \( u_n \) of Eq. (5) satisfies

\[- C \Delta u_n + u_n^3 - \Lambda u_n - \gamma u_n = 0. \]  

(28)

In contrast to bright solitons, where \( u_n \to 0 \) as \( n \to \pm \infty \), dark solitons have \( u_n \to \pm \sqrt[3]{\Lambda + \gamma} \) as \( n \to \pm \infty \).
To examine the stability of $u_n$, we again introduce the linearization ansatz $\phi_n = u_n + \delta u_n$, where again $\delta \ll 1$. Substituting this ansatz into the defocusing equation (5), writing $\epsilon_n(t) = \eta_n + i \xi_n$, and linearizing in $\delta$, we again find

$$\begin{pmatrix} \dot{\eta}_n \\ \dot{\xi}_n \end{pmatrix} = \begin{pmatrix} 0 & L_+ \\ -L_- & 0 \end{pmatrix} \begin{pmatrix} \eta_n \\ \xi_n \end{pmatrix} = \mathcal{H} \begin{pmatrix} \eta_n \\ \xi_n \end{pmatrix},$$

(29)

but where the operators $L_\pm(C)$ are now defined as

$$L_-(C) = - C \Delta_2 + (3 u_n^2 - \Lambda - \gamma),$$

$$L_+(C) = - C \Delta_2 + (u_n^2 - \Lambda + \gamma).$$

The eigenvalue problem above can be simplified further as for the focusing case to the alternative form

$$L_+(C) L_-(C) \eta_n = \omega^2 \eta_n = \Omega \eta_n.$$

(30)

Performing a stability analysis as before, we find the dispersion relation for a dark soliton to be

$$\Omega = [2 C (\cos \kappa - 1) - (\Lambda + 2 \gamma)]^2 - \Lambda^2,$$

(31)

and so the continuous band lies between

$$\Omega_L = 4(\Lambda + \gamma) \gamma, \quad \text{when } \kappa = 0,$$

(32)

and

$$\Omega_U = 4(\Lambda + \gamma) \gamma + 8 C (\Lambda + 2 \gamma + 2 C), \quad \text{when } \kappa = \pi.$$

(33)

FIG. 13. The eigenvalue structure of intersite dark solitons with parameter values as indicated in the caption for each panel.

FIG. 14. (Color online) As Fig. 11, but for an intersite dark soliton. The white dashed line is our analytical approximation (53).
We next investigate the eigenvalues of both intersite and on-site dark solitons, respectively. From Eq. (30), we again expand $\eta_n$ and $\Omega$ in powers of $C$, and hence obtain the eigenvalues $\lambda_n^{(0)}$ and $\lambda_n^{(1)}$ of the parametrically driven Klein-Gordon system (1), with $\epsilon=0.2$. The parameter values are indicated in the caption for each panel. The left and right panels show stable and unstable solitons, respectively.

A. Analytical calculations

To study the eigenvalue(s) of the dark soliton analytically, we expand $\eta_n$ and $\Omega$ in powers of $C$, and hence obtain the eigenvalues $\lambda_n^{(0)}$ and $\lambda_n^{(1)}$ of the parametrically driven Klein-Gordon system (1), with $\epsilon=0.2$. The parameter values are indicated in the caption for each panel. The left and right panels show stable and unstable solitons, respectively.

1. Onsite dark solitons

With errors of order $C^2$, an onsite dark soliton is given by

$$u_n = \begin{cases} -\sqrt{\lambda + \gamma}, & n = -2, -3, \ldots \\ -\sqrt{\lambda + \gamma + \frac{1}{2} C/\sqrt{\lambda + \gamma}}, & n = -1 \\ 0, & n = 0 \\ \sqrt{\lambda + \gamma - \frac{1}{2} C/\sqrt{\lambda + \gamma}}, & n = 1 \\ \sqrt{\lambda + \gamma}, & n = 2, 3, \ldots \end{cases}$$

(38)

For this configuration,

$$\lambda_n^{(0)} = \begin{cases} \lambda^2 - \gamma^2, & n = 0 \\ 4(\lambda + \gamma)^2, & n \neq 0 \end{cases}$$

(39)

From Eq. (34), we then deduce that at $C=0$ the eigenvalues of onsite discrete dark solitons are given by $\Omega_n^{(0)}=4(\lambda + \gamma)^2$, which becomes the continuous band for nonzero $C$, and $\Omega_n^{(0)}=\lambda^2 - \gamma^2$. 

We next investigate the eigenvalues of both intersite and onsite modes.
The solvability condition for Eq. (35) then requires that $f_0=(4\Lambda+\Omega^{(1)})\eta_0^{(0)}=0$. Setting $\eta_0^{(0)}=0$, we deduce that $\Omega^{(1)}=-4\Lambda$. Hence, the eigenvalue of an onsite dark soliton for small $C$ is given by

$$\Omega = \Lambda^2 - \gamma^2 - 4\Lambda C + O(C^2).$$  \hspace{1cm} (41)

Initially, i.e., for $C=0$, the relative positions of the eigenvalue and the continuous spectrum can be divided into two cases, according to whether $\gamma \lesssim \gamma_b = \Lambda/5$. When $C=0$ and $\gamma < \gamma_b \ (\gamma > \gamma_b)$ the eigenvalue (41) will be above (below)

FIG. 16. (Color online) As Fig. 15, but for an intersite bright soliton, with parameter values as indicated in the caption for each panel. The initial profile in each panel corresponds to the same parameters as in Fig. 5.
Note that this critical value is meaningful only when
\[ \gamma = \gamma_{cr,1} \text{,} \]
where
\[ \gamma_{cr,1} = -\frac{2}{3} \Lambda - \frac{8}{3} C + \frac{1}{3} \sqrt{9\Lambda^2 - 28\Lambda C - 16C^2}. \]
(42)

Note that this critical value is meaningful only when \( C \leq 9\Lambda/(4\sqrt{2}) \). For \( \gamma > \gamma_{th} \), the instability is caused by the eigenvalue \( \gamma_{cr,1} \) becoming negative, which occurs when
\[ \gamma = \gamma_{cr,2} \text{,} \]
\[ \gamma_{cr,2} = \sqrt{\Lambda^2 - 4\Lambda C}. \]
(43)

This value is meaningful only when \( C \leq \Lambda/4 \).

Furthermore, if we include terms up to \( O(C^2) \), we obtain
\[ \Omega = \Lambda^2 - \gamma^2 - 4\Lambda C + 6C^2 + O(C^3) \]
(44)
as the eigenvalue of an onsite discrete dark soliton. Using this expression, we find the critical value of \( \gamma \) indicating the onset of instability to be
\[ \gamma_{cr,1} = -\frac{2}{3} \Lambda - \frac{8}{3} C + \frac{1}{3} \sqrt{9\Lambda^2 - 28\Lambda C + 14C^2}, \]
(45)
for \( \gamma < \gamma_{th} \), and
\[ \gamma_{cr,2} = \sqrt{\Lambda^2 - 4\Lambda C + 6C^2}, \]
(46)
for \( \gamma \approx \gamma_{th} \).

2. Intersite modes

Intersite discrete dark solitons are given, with errors of \( O(C^2) \), by
\[ u_n = \left\{ \begin{array}{ll} -\sqrt{\Lambda + \gamma}, & n = -2, -3, \ldots \\ -\sqrt{\Lambda + \gamma + C/\sqrt{\Lambda + \gamma}}, & n = -1 \\ \sqrt{\Lambda + \gamma - C/\sqrt{\Lambda + \gamma}}, & n = 0 \\ \sqrt{\Lambda + \gamma}, & n = 1, 2, \ldots. \end{array} \right. \]
(47)

Starting from Eq. (34), we then find
\[ \mathcal{L}_n(0)\mathcal{L}_{-n}(0) = 4(\Lambda + \gamma)\gamma \]
(48)
for all \( n \), from which we deduce that there is a single leading-order eigenvalue, given by \( \Omega^{(0)} = 4(\Lambda + \gamma)\gamma \), with infinite multiplicity. This eigenvalue then expands to form the continuous spectrum for nonzero \( C \).
Because a localized structure must have an eigenvalue, we infer that an eigenvalue will bifurcate from the lower edge of the continuous spectrum. This bifurcating eigenvalue may be calculated from Eq. (35). Because

$$L_{n}(0) - \Omega(0) = 0$$

for all \( n \), the solvability condition for Eq. (35) requires \( f_n = 0 \) for all \( n \). A simple calculation then yields

$$f_n = \begin{cases} 
[4 \Lambda + 16 \gamma + (2 \Lambda + 4 \gamma) \Delta_2 + \Omega^{(1)}] \eta_n^{(0)}, & n = -1, 0 \\
[(2 \Lambda + 4 \gamma) \Delta_2 + \Omega^{(1)}] \eta_0^{(0)}, & n \neq -1, 0.
\end{cases}$$

Taking \( \eta_n^{(0)} = 0 \) for \( n \neq -1, 0 \) leaves the two nontrivial equations

$$(8 \gamma + \Omega^{(1)}) \eta_0^{(0)} + (2 \Lambda + 4 \gamma) \eta_0^{(0)} = 0,$$

$$(8 \gamma + \Omega^{(1)}) \eta_0^{(0)} + (2 \Lambda + 4 \gamma) \eta_0^{(0)} = 0,$$

from which we see that \( \eta_0^{(0)} = \pm \eta_1^{(0)} \). Thus, we obtain two possibilities for the \( O(C) \) contribution to the eigenvalue, given by

$$\Omega_1^{(1)} = -12 \gamma + 2 \Lambda, \quad \Omega_2^{(1)} = 2 \Lambda - 4 \gamma.$$ 

Hence, the eigenvalues bifurcating from the lower edge of the continuous spectrum are given by

$$\Omega_1 = 4(\Lambda + \gamma) \gamma - (12 \gamma + 2 \Lambda) C + O(C^2),$$

$$\Omega_2 = 4(\Lambda + \gamma) \gamma + (2 \Lambda - 4 \gamma) C + O(C^2).$$

A simple analysis shows that \( \Omega_2 < \Omega_L \) only when \( \gamma > \Lambda/2 \). The sketch in Fig. 8 then illustrates that instability is caused by \( \Omega_1 \) becoming negative. This consideration gives the critical \( \gamma \) as a function of the coupling constant \( C \) to be

$$\gamma_\text{cr} = -\frac{1}{2} \Lambda + \frac{3}{2} C + \frac{1}{2} \sqrt{\Lambda^2 - 4 \Lambda C + 9 C^2}.$$ 

When there are two eigenvalues (\( \Omega_1 \) and \( \Omega_2 \)), \( \Omega_2 \) decreases more slowly than \( \Omega_1 \), in such a way that for \( \gamma > \Lambda/2 \) the instability is still caused by \( \Omega_1 \) becoming negative.

B. Comparison with numerical computations

I. Onsite dark solitons

We now compare our analytical results with corresponding numerical calculations. As for bright solitons, for illustrative purposes we set \( \Lambda = 1 \).

We start by checking the validity of our analytical approximation for the critical eigenvalue associated with the phase mode. As explained above, the change in the position of the eigenvalues relative to the continuous spectrum at \( C = 0 \) occurs at \( \gamma = 1/5 \). Therefore, we consider the two values \( \gamma = 0.1 \) and 0.6, representing both cases. Figure 9 depicts a comparison between our analytical result (41) and the numerical computations, from which we conclude that the prediction is quite accurate for small \( C \). The accuracy can be improved if one includes further orders in the perturbative expansion (44), and this improvement is shown in the same figure by the dotted line.

The eigenvalue structure of onsite dark solitons is depicted in Fig. 10; left and right panels refer, respectively, to conditions just before and just after a collision resulting in an instability. As sketched in Fig. 7, for \( \gamma < 1 \) the instability is caused by a collision between the eigenvalue and one edge of the continuous spectrum. On the other hand, when \( \gamma \approx 1/5 \) the instability is caused by a collision between the eigenvalue and its twin at the origin (see the bottom panels of Fig. 10).

We now proceed to evaluate the (in)stability region of this solution in the \( (C, \gamma) \) plane. Shown in Fig. 11 is again the maximum of the imaginary part of the eigenvalue, together with our approximation to the (in)stability boundary. The white solid line represents Eq. (43), corresponding to the instability caused by the collision with the continuous spectrum. Equation (42) is represented by the white dashed-dotted line, which corresponds to the other instability mechanisms. In addition, white dashed and dotted lines show, respectively, Eqs. (46) and (45), where a better analytical approximation is obtained.

An important observation from Fig. 11 is that there is an interval of values of \( \gamma \) in which the onsite dark soliton is
always stable, for any value of the coupling constant $C$. This indicates that a parametric driving can fully suppress the oscillatory instability reported for the first time in [22].

2. Intersite dark solitons

Now we examine intersite dark solitons. First, Fig. 12 shows the analytical prediction for the critical eigenvalue, given by Eq. (51), compared to numerical results. We see that the approximation is excellent for small $C$ and its range of validity is wider for larger values of $\gamma$. The eigenvalue structure of this configuration is shown in Fig. 13 for the two values $\gamma=0.1, 0.8$. The mechanism of instability explained in the section above can be seen clearly in the top panels of Fig. 13.

It is interesting to note that a parametric driving can also fully suppress the oscillatory instability of an intersite dark soliton. As shown in the bottom panels of Fig. 13, there are values of the parameter $\gamma$ for which no instability-inducing collision ever occurs. The (in)stability region of this configuration is summarized in Fig. 14, where we see that for any $C$ and $\gamma \geq 0.3$ an intersite dark soliton is always stable. Our analytical prediction for the onset of instability is given by the dashed line in Fig. 14. We observe that for relatively small $C$, the prediction of Eq. (51) is reasonably close to the numerical results.

IV. DISCUSSION

In the sections above we discussed the existence and the stability of localized modes through our reduced DNLS (5). In this section, we confirm the relevance of our findings through solving numerically the original time-dependent equation (1). We use a Runge-Kutta integration method, with the initial condition $\varphi_n=2\epsilon u_n$ and $\varphi_n=0$, where $u_n$ is the static solution of the DNLS (5) and $\epsilon$ is the small parameter of Sec. I. Throughout this section, we use the illustrative value $\epsilon=0.2$.

Shown in the left and right panels of Fig. 15 are the numerical evolution of stable and unstable onsite bright solitons, respectively. From the top right panel of the figure, we note that a parametric driving seems to destroy an unstable soliton. This observation is similar to the corresponding observation for the dynamics of an unstable soliton in the DNLS (5) reported in Ref. [26]. In the bottom right panel, we present another case of unstable dynamics for a relatively large parametric driving amplitude $\gamma$, where the bright soliton is seemingly still preserved but having a different oscillation frequency and amplitude.

In Fig. 16 we present the numerical evolution of intersite bright solitons for the same parameter values as those in Fig. 5, corresponding to each of the instability scenarios. From the panels in Fig. 16, we see that the typical dynamics of the instability is in the form of soliton destruction or discharge of a traveling breather.

We have also examined the dynamics of onsite dark solitons in the Klein–Gordon system (1). Shown in Fig. 17 is the numerical evolution of a solution with the eigenvalue structure illustrated in Fig. 10. The instability of an unstable onsite dark soliton typically manifests itself in the form of oscillations in the location of the soliton center about its initial position (top right panel) or oscillations in the width of the soliton (bottom right panel).

Finally, we illustrate the dynamical behavior of an unstable intersite dark soliton in Fig. 18, from which we see that the instability makes the soliton travel. This dynamics is similar to that reported in Ref. [21].

V. CONCLUSION

In this paper, we have considered a parametrically driven Klein–Gordon system describing nanoelectromechanical systems. Using a multiscale expansion method we have reduced the system to a parametrically driven discrete nonlinear Schrödinger equation. Analytical and numerical calculations have been performed to determine the existence and stability of fundamental bright and dark discrete solitons in the Klein–Gordon system through the use of the Schrödinger equation. We have shown that the presence of a parametric driving can destabilize an onsite bright soliton. On the other hand, a parametric driving has also been shown to stabilize intersite bright and dark discrete solitons. We even found an interval in $\gamma$ for which a discrete dark soliton is stable for any value of the coupling constant, i.e., a parametric driving can suppress oscillatory instabilities. Stability windows for all the fundamental solitons have been presented and approximations using perturbation theory have been derived to accompany the numerical results. Numerical integrations of the original Klein–Gordon system have demonstrated that our analytical and numerical investigations of the discrete nonlinear Schrödinger equation provide a useful guide to the behavior in the original system.

We note that by the staggering transformation $\phi_n \rightarrow (-1)^n \phi_n$, and $\Lambda \rightarrow (\Lambda + 4C)$ the DNLS (5) with defocusing nonlinearity can be transformed into Eq. (5) with focusing nonlinearity. This implies that, according to the reduced equation (5), staggered bright and dark solitons can also exist in the DNLS with defocusing and focusing nonlinearities, respectively. It is noteworthy that such a transformation is not immediately present in the original governing equation (1), a situation similar to that reported in, e.g., [38]. This seemingly paradoxical fact will be studied in a future work. In a number of preliminary simulations, we have found that when a staggered localized mode obtained from Eq. (5) is used as an initial solution to Eq. (1), it proves relatively short lived, compared to the time scale presented in the figures herein. We also propose to study further the influence of the higher oscillation frequency modes, which are neglected in the derivation of Eq. (5) from Eq. (1).
